OBJECTIVES

1. At participating in this program, learners will be able to describe the strengths and limitations of screening tools to identify ADHD

2. At participating in this program, learners will be able to describe the general components of a comprehensive assessment for ADHD

3. At participating in this program, learners will be able several key aspects to successfully monitoring ADHD treatment response
ADHD AS A SOURCE OF CONTROVERSY...

• NY Times search of “ADHD”:
  – Thousands of Toddlers are Medicated for ADHD (May 2014)
  – Reports Says Medications Use is Rising for Adults with ADHD (May 2014)
  – Expand Pre-K, Not ADHD (February 2014)
  – Untangling the Myths About Attention Disorder (March 2016)

Other media:
CAN OVER-STIMULATION (E.G., EXPOSURE TO RAPIDLY PACED TELEVISION PROGRAMS IN THE FIRST 3 YEARS OF LIFE) INCREASE THE RISK OF ATTENTIONAL DEFICITS AT SCHOOL AGE?

Rethinking Attention-Deficit/Hyperactivity Disorder

The prevalence of attention-deficit/hyperactivity disorder (ADHD) has increased substantially over the past 20 years; by some estimates, as much as 30%.

Much like the rise in autism prevalence, the reasons for this are likely multifactorial, including an actual rise in incidence as well as increased recognition and diagnosis. The deficits seen in children with ADHD include impulsivity and inattention, and these salient features are part of what those of us researching cognition consider “executive function.”

testing for ADHD, we dichotomize a continuous variable: we draw a line at some point on that curve, typically at the 95th percentile, and define that as what distinguishes pathology from normalcy. In the case of ADHD, a clinician performs a series of assessments by having parents and teachers report their observations of the child on a standardized form. In one of the most widely used and well-validated measures of ADHD, a child needs to demonstrate 6 of 9 specific behaviors to be diagnosed as having ADHD. Each of those behav-
Should We Be Thinking of Adult ADHD By Comparing It to Type-2 Diabetes?

Is Adult ADHD a Childhood-Onset Neurodevelopmental Disorder? Evidence From a Four-Decade Longitudinal Cohort Study

Terrie E. Moffitt, Ph.D., Renate Houts, Ph.D., Philip Asherson, M.D., Daniel W. Belsky, Ph.D., David L. Corcoran, Ph.D., Maggie Hammerle, B.A., Honalee Harrington, B.A., Sean Hogan, M.S.W., Madeline H. Meier, Ph.D., Guilherme V. Polanczyk, M.D., Richie Poulton, Ph.D., Sandhya Ramrakha, Ph.D., Karen Sugden, Ph.D., Benjamin Williams, B.A., Luis Augusto Rohde, M.D., Avshalom Caspi, Ph.D.

Objective: Despite a prevailing assumption that adult ADHD is a childhood-onset neurodevelopmental disorder, no prospective longitudinal study has described the childhoods of the adult ADHD population. The authors report follow-back analyses of ADHD cases diagnosed in adulthood, alongside follow-forward analyses of ADHD cases diagnosed in childhood, in one cohort.

Method: Participants belonged to a representative birth cohort of 1,037 individuals born in Dunedin, New Zealand, in 1972 and 1973 and followed to age 38, with 95% retention. Symptoms of ADHD, associated clinical features, comorbid disorders, neuro-psychological deficits, genome-wide association study-derived polygenic risk, and life impairment indicators were assessed. Data sources were participants, parents, teachers, informants, neuro-psychological test results, and administrative records. Adult ADHD diagnoses used DSM-5 criteria, apart from onset age and cross-setting corroboration, which were study outcome measures.

Results: As expected, childhood ADHD had a prevalence of 6% (predominantly male) and was associated with childhood comorbid disorders, neurocognitive deficits, polygenic risk, and residual adult life impairment. Also as expected, adult ADHD had a prevalence of 3% (gender balanced) and was associated with adult substance dependence, adult life impairment, and treatment contact. Unexpectedly, the childhood ADHD and adult ADHD groups comprised virtually nonoverlapping sets; 90% of adult ADHD cases lacked a history of childhood ADHD. Also unexpectedly, the adult ADHD group did not show tested neuropsychological deficits in childhood or adulthood, nor did they show polygenic risk for childhood ADHD.

Conclusions: The findings raise the possibility that adults presenting with the ADHD symptom picture may not have a childhood-onset neurodevelopmental disorder. If this finding is replicated, then the disorder’s place in the classification system must be reconsidered, and research must investigate the etiology of adult ADHD.

PREVALENCE AND PROGNOSIS

• Prevalence 6-9% (2x boys); 4-5% in adults
• Adult prevalence approximately ½ of youth prevalence
• Many will have symptoms persisting into adulthood.
  – As many as 90% will still have some symptoms of ADHD, not necessarily meeting strict diagnostic criteria.
• Long-term consequences of ADHD:
  – Higher rates of traffic and other accidents, marital difficulties, unemployment, antisocial and criminal behavior, and obesity.
  – Lower household income attained
  – Higher rates of attempted and completed suicide

DSM-5 DIAGNOSTIC CRITERIA AND THE FUNCTION OF SCREENING TOOLS
DIAGNOSIS

• Before 12 yo (versus prior to age 7 in DSM-IV)
• 6 months duration
• 2 or more settings
• Clinically significant impairment
• Not explained by other disorder
• 6 symptoms of inattention or hyperactivity or both
  – Other DSM-5 updates: 5 symptoms for adults, examples included to facilitate diagnoses across the life span, cross-situational requirement strengthened to include several symptoms in each setting, subtypes replaced with specifiers (which map to previous subtypes), autism is no longer an exclusionary comorbid diagnosis

INATTENTION

• Lacks attention to detail/careless mistakes
• Difficulty sustaining attention
• Does not seem to listen when spoken to
• Poor follow through
• Difficulty with organization
• Avoids tasks requiring sustained mental effort
• Loses things
• Easily distracted
• Forgetful

HYPERACTIVITY/IMPULSIVITY

- Blurts out answers before question completed
- Runs/climbs excessively (restless in adolescents)
- Difficulty staying in seat
- Difficulty engaging in quiet activities
- “On the go”
- Talks excessively
- Interrupts
- Difficulty awaiting turn
- Fidgets

ACCURATE DIAGNOSES AND THE ROLE OF RATING SCALES

• Over-reliance on parent- and teacher-completed rating scales during the assessment process may lead to inaccurate diagnoses.

• ADHD rating scales have only moderate sensitivity while their specificity ranges from low to moderate.

• Additionally, there is often poor agreement between parent and teacher responses. With these limitations in mind, it is important to remember that rating scales are best used as screening tools and to measure treatment response.

• Rating scales are best used as screening tools and to measure treatment response.
CENTRAL ROLE OF IMPAIRMENT IN ASSESSMENT AND TREATMENT

- **Impairment**--that is, problems in daily life functioning that result from symptoms (rather than symptoms themselves) are what should be targeted in treatment

- **Assessment of impairment** in daily life functioning is a fundamental aspect of initial evaluation

- **Ongoing assessment** of impairment in critical domains is necessary to determine the impact of and need for modifications in treatment

- Normalization or **minimization of impairment** in daily life functioning is the **goal of treatment**
QUESTIONS TO HELP ELICIT IMPAIRMENT

• Evaluate the burden of symptoms
  • Does it show up differently in roles or contexts?
  • Is it an effort to compensate for?
• Consider impairment relative to potential
  How would individual function if symptoms resolved?
  • Is there mismatch with role/environment?
  Would change in role or environment remedy?
• Is concern exaggerated?
  Unrealistic parental or individual expectations / perfectionistic / inaccurate self-evaluation
SUMMARY OF KEY ADHD SCREENING POINTS

• ADHD is both underdiagnosed and over-diagnosed in different populations and should be routinely screened for during regular office visits, especially if there are concerns for poor concentration and functional achievement below expected potential

• Adults with concerns for ADHD may not have been diagnosed as children and may present with different complaints/symptoms

• Often exists with other co-morbid illnesses but symptoms may also represent a ADHD “mimic;” both should be screened for

• Secondary gain may play a part in diagnostic picture

• Determining level of functional impairment is critical
BEYOND SCREENING TOOLS: ADDITIONAL WORKUP CONSIDERATIONS
WORK-UP

• In general, no testing or imaging is indicated.
• Clinical diagnosis
  – But some soft physical signs may be present, such as motor overflow and clumsiness.
• Rating scales can help elicit symptoms.
• Comparison to peers
  – Inattention/hyperactivity common in preschoolers.
• Response to stimulants is not unique to individuals with ADHD.
• Consider psychological or neuropsychological testing if low cognitive ability or achievement relative to ability.

WORK-UP

• If other symptoms present, consider
  – Lead
  – Thyroid and other endocrine (eg, low testosterone in adults)
  – Seizures
  – OSA
  – Anemia
  – Trauma
  – Substance abuse
  – Sensory impairment
  – Brain injury
  – Genetic syndrome

• Medication side effects may mimic ADHD.
  – Bronchodilators
  – Corticosteroids
  – Antihistamines
  – Antipsychotics
COMORBIDITY VS. ADHD MIMICS
PSYCHIATRIC MIMICS

- Autism Spectrum Disorder
- Intellectual Disability (not obvious)
- Depression (not comorbid)
- Anxiety and OCD
- Bipolar disorder (especially in adults)
- Eating Disorder
- Adjustment disorders
- ADHD personality (symptoms without impairment)
- Stimulant seeking (abuse, anorexia)
- Other substance abuse
OTHER FACTORS

– Poor fit between temperament, environment, and expectations
– Mercer Island ADHD
– Marital dissatisfaction and other stressors
– Chaotic environments
– Fad?
– Excuse?
COMMON CHILDHOOD COMORBIDITIES

- Language or Learning problem (25-35%)
- ODD (55-85%)
- Substance abuse (20-40%)
- Conduct (10-20%)
- Anxiety (33%)
- Tic disorder (50%)
- Mood disorders
- Sleep problems

ADULT COMORBIDITIES ARE COMMON AS WELL

12 Month Comorbidity: 18 - 44 Year Old Adults

Kessler et al, 2006

p < .05 vs. No ADHD
ADHD AND COMPLETED SUICIDE IN SCHOOL-AGED CHILDREN: A CONNECTION?

Suicide in Elementary School-Aged Children and Early Adolescents

Arielle H. Shaftall, PhD,† Lindsey Asti, MPH,† Lisa M. Horowitz, PhD, MPH,§ Adrienne Felts, MA, PCC,§ Cynthia A. Fontanella, PhD,‡ John V. Campo, MD,∥ Jeffrey A. Bridge, PhD∥§

**abstract**

**BACKGROUND AND OBJECTIVES:** Suicide in elementary school-aged children is not well studied, despite a recent increase in the suicide rate among US black children. The objectives of this study were to describe characteristics and precipitating circumstances of suicide in elementary school-aged children relative to early adolescent decedents and identify potential within-group racial differences.

**METHODS:** We analyzed National Violent Death Reporting System (NVDRS) surveillance data capturing suicide deaths from 2003 to 2012 for 17 US states. Participants included all suicide decedents aged 5 to 14 years \( (N = 693) \). Age group comparisons (5–11 years and 12–14 years) were conducted by using the \( \chi^2 \) test or Fisher’s exact test, as appropriate.

**RESULTS:** Compared with early adolescents who died by suicide, children who died by suicide were more commonly male, black, died by hanging/strangulation/suffocation, and died at home. Children who died by suicide more often experienced relationship problems with family members/friends \( (60.3\% \text{ vs } 46.0\%; \ P = .02) \) and less often experienced boyfriend/girlfriend problems \( (0\% \text{ vs } 16.0\%; \ P < .001) \) or left a suicide note \( (7.7\% \text{ vs } 30.2\%; \ P < .001) \). Among suicide decedents with known mental health problems \( (n = 210) \), childhood decedents more often experienced attention-deficit disorder with or without hyperactivity \( (59.3\% \text{ vs } 29.0\%; \ P = .002) \) and less often experienced depression/dysthymia \( (33.3\% \text{ vs } 65.6\%; \ P = .001) \) compared with early adolescent decedents.

**CONCLUSIONS:** These findings raise questions about impulsive responding to psychosocial adversity in younger suicide decedents, and they suggest a need for both common and developmentally-specific suicide prevention strategies during the elementary school-aged and early adolescent years. Further research should investigate factors associated with the recent increase in suicide rates among black children.
ADHD AND SUBSTANCE ABUSE

- ADHD diagnosis increases the risk of substance use and nicotine dependence.
- Early stimulant treatment may reduce or delay the onset of substance use disorder.
  - Recent follow up data from the MTA revealed no harm or benefit from medication treatment in regard to rates of adolescent substance abuse.

ADHD AND SUBSTANCE ABUSE

• Stimulant misuse rates of 5-9% for grade school and high school (and 5-35% in college-age individuals)
• Consider longer-acting formulations, lisdexamfetamine, and atomoxetine.
• ADHD medications used for adolescents with active substance abuse are not as effective.

TREATMENT MONITORING
TREATMENT MONITORING

• Symptoms may improve over time but oftentimes impairment persists even if attenuated
• Medication non-compliance is common; monitor for abuse and/or diversion
• Consider use of long-acting stimulants and/or non-stimulants for patients with substance abuse histories.
• Important to follow consensus guidelines, including frequent use of follow-up rating scales
• Help patients develop clear treatment goals so that expectations are reasonable and functional improvement can be measured
• Collect collateral data both during diagnostic phase and during outcome monitoring
AGE-DEPENDENT DECLINE OF ADHD SYMPTOMS

Age-specific prevalence of remission from ADHD among 138 boys, according to definition of remission and symptom type.
Variability in ADHD Care in Community-Based Pediatrics

- 93% received medication, 13% received psychosocial treatment
- Half using rating scales during assessment
- Variability at patient but also practice level
- “Almost no ADHD care follows ADHD consensus guideline recommendations for treatment”
- “the proportion of children receiving psychosocial treatment was miniscule”

MEDICATION ADHERENCE AND CONTINUITY

• ½ of the children experienced their first 30-day gap in medication supply within the first 3 months of treatment
• Fewer than ½ of the parents had contact with their physicians within the first month of medication initiation with the average time being greater than 2 months
• The average time to the first medication change was over 3 months.
• Results indicated that early physician contact and titration were related to greater continuity and medication supply over a period of 1 year

SUMMARY OF KEY POINTS

• ADHD is:
  – Highly prevalent (8%-10% of children and adolescents; 4%-5% of adults)
  – Familial
  – Neurobiologically-based but environmentally influenced
  – Range of severity, mild to chronic and debilitating (substantial comorbidity; severe academic, occupational, personal consequences)
  – Often chronic but symptoms may decline but impairments remain or even increase over time due to cumulative effect of illness
DIAGNOSIS

– Complicated by heterogeneity, age, method, and practice issues
– Absence of biomarker does not equate with subjectivity
– Rating scales are diagnostic tools but do not meet the standard of a laboratory test, especially in terms of specificity
– Further workup (eg, neuropsych testing, specialty referrals) may can be helpful for mimics and comorbidity
– Impairment is central and guides treatment
